## 1 **R.18 EXPOSURE ASSESSMENT FOR THE WASTE LIFE STAGE**

### 2 **R.18.1 Aim of this chapter**

3 This chapter is intended to provide guidance to M/I how to identify the conditions under which the  
4 waste arising from the manufacture and use of a substance can be safely handled and disposed of.  
5 Section D.3.6.2.6 had its focus on highlighting the operational conditions of use and substance  
6 properties that may result in particular risks related to the waste life stage, and what risk manage-  
7 ment measures would be suitable. Also the different types of waste being generated during the life-  
8 cycle are briefly explained.

9  
10 The current chapter aims to systematically guide M/I on how to build exposure scenarios for the  
11 waste life stage. This includes:

- 12 • Explanation related to the legal requirements
- 13 • Illustrating the scope of what has to be covered related to the waste life stage
- 14 • Giving guidance on the principal workflow to carry out exposure scenario building and expo-  
15 sure estimate for the waste life stage
- 16 • Apply the Environmental release classes (ERCs) as a tier 1 exposure estimations tool suitable to  
17 establish whether releases from the waste life stage may lead to uncontrolled risks and hence  
18 need more in-depth assessment in the CSA.
- 19 • Illustrate how an exposure scenario for the waste life stage may look like.

### 21 **R.18.2 Obligations to assess the waste life stage under REACH**

22 Waste as defined in Directive 2006/12/EC of the European Parliament and of the Council<sup>1</sup> is *not a*  
23 *substance, preparation or article under REACH* (Article 2(4)). Thus, companies handling sub-  
24 stances in waste are neither downstream users nor recipients of articles, and consequently they do  
25 not have any duties under REACH.

26 Nevertheless manufacturers and importers of substances, downstream users and eventually recipi-  
27 ents of articles have a number of duties under REACH related to waste.

- 28 • M/I shall document in the registration dossier available information on the amount of waste re-  
29 sulting from manufacture of the substance, from the identified uses and from use in articles, in-  
30 cluding composition of the waste streams.
- 31 • For dangerous substances > 10 t/a, the waste life-stages resulting from manufacture and use  
32 need to be covered in M/I's chemical safety assessment (see Annex I of REACH), including  
33 exposure estimation, and measures for safe handling to be communicated downstream in the  
34 exposure scenario and under chapter 13 of the extended safety data sheet (see Annex II).

35  
36 Consequently, it is the duty of downstream users i) to consider the waste life-stage related informa-  
37 tion received with the exposure scenario, ii) to take action in case the internal handling of waste and  
38 the chosen route for disposal is outside the conditions set in the ES, and iii) to communicate the

---

<sup>1</sup> OJ L 114, 27.4.2006, p. 9.

39 relevant information to further downstream users.. The tasks for MI and DU under REACH with  
40 regard to handling of waste are limited to the following:

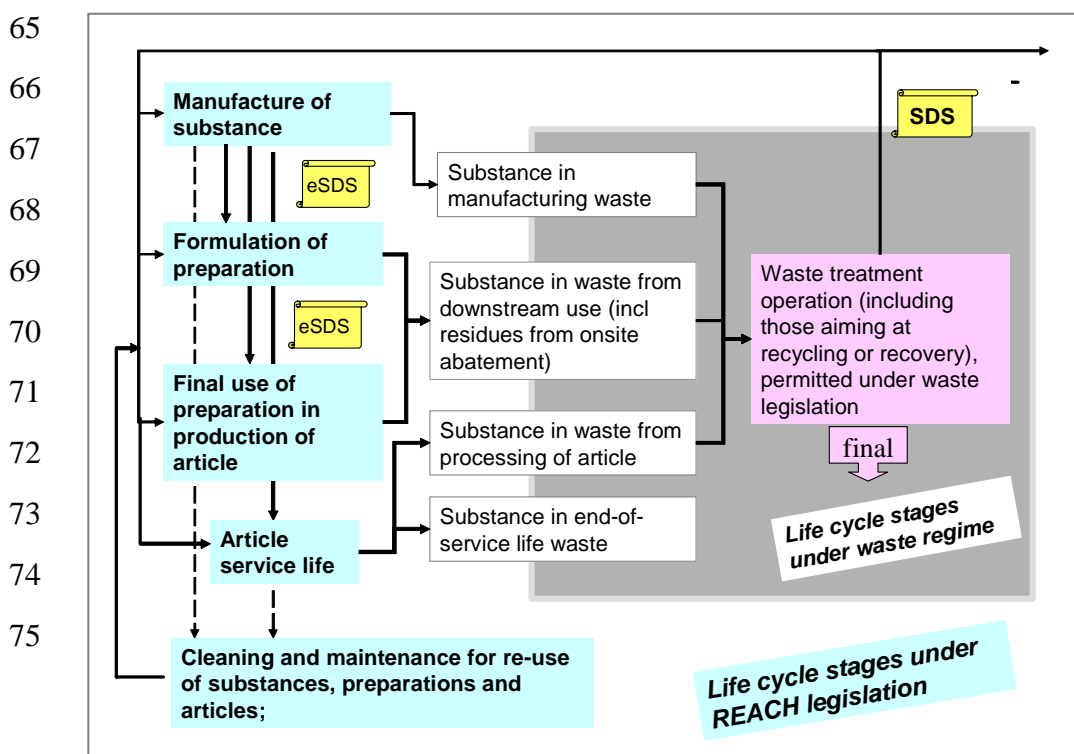

- 41 • Implement waste related measures with regard to M/I's or DU's own activity, as stated in the  
42 exposure scenario.
- 43 • Forward waste related information received with the ES from the supplier to the next down-  
44 stream user.
- 45 • Choose external waste treatment operations, in line with what is recommended in the supplier's  
46 exposure scenario.

47

48 Figure R.18-2.1 illustrates the scope of the waste related considerations in the CSA and the infor-  
49 mation mechanisms in the supply chain. **Please consider the following clarifications on the scope**  
50 **of waste in the CSA:**

- 51 • Internal handling of substances in waste to be disposed of in external operations is still part of  
52 downstream use under REACH. This regards for example occupational and environmental  
53 measures to prevent exposure from internal collection and storage of waste, and onsite pre-  
54 treatment of residues for example by extracting water.
- 55 • The waste regime begins, and hence duties under REACH end, when the residues have been  
56 transferred into the responsibility of an authorised waste management company.
- 57 • Cleaning and regeneration of contaminated/spent processing aids or product aids (e.g. re-  
58 destillation of cleaners, washing of cleaning wipes) outside waste legislation is regarded a  
59 downstream use under REACH. Such operations will not be covered in this section.
- 60 • Residues that may occur in onsite pre-treatment of waste-water and exhaust air (= result of envi-  
61 ronmental risk management measures) and which are to be disposed of in external waste treat-  
62 ment facilities are to be covered in the waste management section of the relevant exposure sce-  
63 narios.

64 **Figure R.18-1: Interface between REACH and waste legislation**

### 76 **R.18.3 Sources and emission pathways from waste treatment and recycling**

#### 77 **Sources**

78 Emissions from waste can occur via air, water and soil and are estimated for every environmental  
79 compartment and each relevant stage of the life cycle separately. Waste treatment may include re-  
80 covery, chemical-physical treatment, incineration or disposal at landfills (see Figure R.18.3-1).

81 The direct release to soil is only considered at a regional scale. The split of releases between the  
82 different waste streams depends on the chem.-phys properties of the substances in combination with  
83 the process parameters in the relevant uses. The section below will give more detailed information  
84 on the emission pathways from waste treatment and recycling.

85 Substances may enter the waste life stage in the following form (see figure R.18.2-1):

- 86 • in residues from manufacture of a substance
- 87 • in residues from formulating preparations (e.g. cleaning operations, low quality charges)
- 88 • in residues from use of preparations (e.g. spent lubricants, overspray from coating, contaminated  
89 packages)
- 90 • in residues from production and processing of articles (e.g. discarded paper material from print  
91 shops, discarded plastic material or metal from cutting or drilling)
- 92 • in residues from onsite treatment of waste water or waste gas
- 93 • in articles at the end of their service life.

94

#### 95 **Recycling and recovery**

96 Recovery processes usually involve a homogenisation and/or separation step (e.g. mechanical  
97 treatment) followed by recovery of the target substance/material. The recovered substance or mate-  
98 rial may be:

- 99 • reprocessed for the original type of product (recycling);
- 100 • processed into a new type of product;
- 101 • used as secondary fuel in heat production (energy recovery).

102

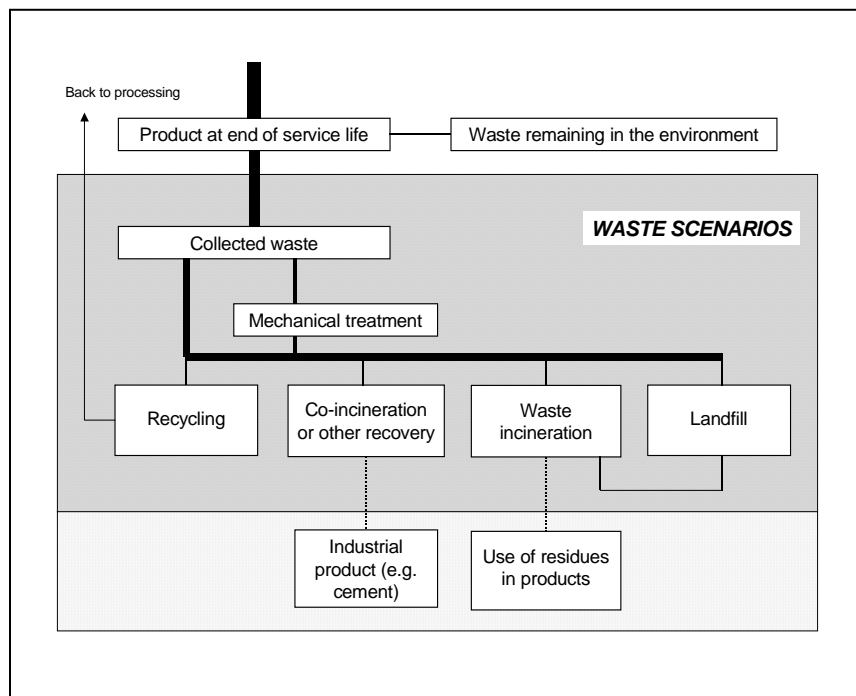

103 In the first option the substance returns into life-cycle stages already assessed before. In the second  
104 and third option the substance may enter into processing and final products from which new types  
105 and amounts of releases could occur. Unless benefiting from the exemptions in article 2(7)d (see  
106 Appendix R.18-3), for companies re-introducing substances in products made from waste into the  
107 market, the REACH obligation related to manufacturing/import of substances apply.

108 In some cases, another substance or product may be recycled, and the substance assessed is present  
109 in this product as a contamination. An organic substance present in a photographic bath for exam-  
110 ple, will be discharged to waste after silver recovery. A substance present in printing ink will be re-  
111 leased with wastewater and de-inking sludge at paper recycling.

112 In addition to being recovered, incinerated or disposed of in landfills, substances in articles at the  
113 end of their service life may be released, either intentionally or unintentionally, to the environment.  
114 They may intentionally be left in the environment after their service life (e.g. cables buried in soil).  
115 Fragments of articles may also be lost during use (e.g. paint flakes, car undercoating). The emission  
116 during this life-cycle stage are addressed in chapter R.17.

**Figure R.18-2: Waste life stage of a substance**

For substances that could form toxic and/or persistent degradation products under the waste treatment e.g. due to thermal stress or incomplete combustion, an assessment is needed how to minimise or prevent such emissions in the waste life stage.

131

145  
146  
147

1. Select the life cycle stage (LCS) for which the waste treatment should be examined; consult the exposure scenarios already developed for information on use conditions of the substance as such, in a preparation or in an article for the selected LCS. The type of use (see descriptor system) may help to identify i) suitable waste category from the European waste list (EWL) and ii) waste categories with special EU requirements under waste regulation. Where no information is available, contact representative customers. The **Outputs are:**
  - Types of chemical products and articles that may become waste during the life cycle.
  - Identification of residues from environmental risk management measures applied during the life cycle.
  - Relevant requirements from EU waste legislation with regard to particular waste streams.
2. Document available information on the amount and the nature of generated waste; quantify the waste streams for the selected use; if necessary use a mass balance scheme for the quantification of waste streams. Check whether the substance may cause particular, waste related risks not yet covered in any of the ES for the other life cycle stages (see checklist under D 3.6.2.6).

- 148 3. Select one of the general waste management strategies that will be applied for the identified  
149 waste streams: chemical-physical treatment; destruction by incineration or co-incineration,  
150 landfill, recycling as material, recovery as fuel; consider if an EU waste legislation is avail-  
151 able that regulates the treatment techniques to be applied; identify requirements for best  
152 available technique in the corresponding BREF Document (see Appendix R.18-1). The  
153 **Outputs are:**
- 154 • Identification of particular risks that may occur in the waste life stage of the substance  
155 and the corresponding need for particular advice to be communicate to downstream us-  
156 ers
  - 157 • Waste quantities and concentration of substances for waste stream of particular concern
  - 158 • Identification of suitable/required waste management strategies and/or techniques to be  
159 documented in the CSR.
- 160 4. Insert relevant information into the initial exposure scenario or select an available generic  
161 standard exposure scenario for the relevant waste operation. **Output:** First draft of initial  
162 exposure scenario related to the waste life stage.
- 163 5. If the available information does not provide a basis to carry out an emission estimate, as-  
164 sign an *environmental release category* (ERC) or more specific pre-set for the selected  
165 treatment operation. Section R.18.5 and appendix R.18.1 provides guidance on: i) Emission  
166 estimation of organic substances and metals from waste incineration, co-incineration and  
167 landfills, ii) emission estimation for dismantling of articles after service life and iii) any  
168 waste operation that can be assigned to one of the environmental release classes (ERCS)  
169 (see appendix R.16-1 and chapter R.16.2). Feed in information on the quantity of waste and  
170 the concentration of substance in that waste (from step 2), in order to arrive at a release es-  
171 timate. If contacts with the waste treatment company exist, cross check whether the release  
172 estimate is reasonable. The **Output is:**
- 173 • Tier 1 release estimates that can be fed into exposure estimation and risk characterisa-  
174 tion.
- 175 6. If the comparison with relevant DNELs indicates that control of risk cannot be established  
176 based on the initial run of the tier 1 release estimates, further collection of available informa-  
177 tion may be needed: Literature; communication with downstream users; communication  
178 with waste management industries at a voluntary level. Iterate the CSA with the additional  
179 information.
- 180 7. Refine and complete the exposure scenario with information identified when assigning and  
181 adjusting the relevant ERCS, for example: fraction of waste life stage volume, amount of  
182 substance in waste per treatment site, more realistic emission factors.
- 183 8. Carry out a risk characterisation and derive the final exposure scenario information
- 184 9. Include the use specific waste management advice into section 7 of the exposure scenarios  
185 annexed to the extended safety data sheet. Include a summary of the relevant information  
186 into section 13 of the extended safety data sheet. Include the standard exposure scenarios for  
187 the relevant waste treatment operations into the annex of the safety data sheet.

188  
189 Based on the workflow described, exposure scenarios covering the waste operations relevant for the  
190 identified use of the substance can be developed. The recommended standard formats are contain in  
191 appendix R.18-2.. This includes

- 192 1. advice on handling and disposal in the exposure scenario related to a certain use (section 7  
193 of the ES) and
- 194 2. generic exposure scenarios related to certain waste treatment techniques.

195 Occupational risk management measures in waste treatment and waste handling can be identified  
196 via the risk management library (see section D.3.6.6)<sup>2</sup>. Occupational exposure during waste treat-  
197 ment operation can be assessed based on the tier 1 tools described in section D.4.1, since waste op-  
198 erations do not principally differ from processes applied in industrial and professional processing.  
199 The descriptor 3 of the use descriptor system (see Table 2 in appendix D-1) may support the inte-  
200 gration of risk management advice into the generic exposure scenarios related to waste operations.

## 201 **R.18.5 Tier 1 Emission estimation**

### 202 **R.18.5.1 Pre-sets for the emission pattern in time and space**

203 Emissions to the environment from the waste life stage of a substance have to be considered in the  
204 registrant's chemicals safety assessment. If particular risks related to emissions from the waste life  
205 stage need to be controlled, REACH requires the registrant to communicate appropriate measures  
206 down the supply chain in order to enable the final downstream user in the chain to dispose of the  
207 waste accordingly. The following section provides guidance on how M/I can identify releases of the  
208 substance from the waste life stage into the environment. The ERCs are used as a starting point to  
209 derive the input to a first tier exposure estimation. For the most abundant waste operations, appen-  
210 dix R.18-1 gives an overview on information sources that may contain information, from which  
211 emission factors can be derived. Most of the waste operations can be assigned to an environmental  
212 release category (ERCs), based on similarities in conditions of use related to processes and prod-  
213 ucts.

214 Releases from the waste life stage may occur several decades after production and processing of the  
215 substance under assessment. These delays are determined, inter alia, by:

- 216 • the service life span of the substance as such, or in a chemical product or article;
- 217 • intermediate storage after service life before waste collection (e.g. exhausted batteries);
- 218 • exposure of residues (secondary waste) from waste incineration to water. This source could be  
219 of particular relevance if the residues are re-introduced into the market as products (e.g. building  
220 material) exposed to water;
- 221 • exposure of waste in landfills to water.

222  
223 Thus, when carrying out the CSA, the registrant needs to consider the time pattern of releases. This  
224 should be done by applying the following rules:

- 225 • Project the releases from the waste life stage into the year when marketing of the substance  
226 takes place, in order to take account of the stocking up processes (see Chapter R.17). Assume  
227 steady state: What is disposed of will be replaced with a new product containing the same sub-  
228 stance.

---

<sup>2</sup> Four guidance documents related to occupational risks in waste operations have been identified in Germany: Classification and labelling related to handling of waste to be disposed of (TRGS 201, July 2002). Guidance related to the handling of dangerous chemical in recycling of end-of-life-vehicles (LASI/ALMA recommendation 26, 2002); Guidance related to manual dismantling of screens and electric devices (LASI/ALMA recommendation 27, 2002); Guidance related to recycling of plastic (LASI/ALMA recommendation 32).

- 229 • If applicable, include building material produced from residues of waste incineration into the  
 230 release estimates from the waste life stage
- 231 • Assume a landfill situation where the properties are based on construction waste (no capture of  
 232 fugitive emissions, rain water and radiation access to the waste, waste water collection), since  
 233 bio-reacting landfills will not be allowed anymore under the EU Landfill Directive. Assume that  
 234 the conditions are similar to outdoor use of construction material.
- 235 The registrant also needs to consider, which fraction of his market volume enters into the waste life  
 236 stage (fraction of waste life volume). The following differentiation can be made for a tier 1 release  
 237 estimate:

- 238 • For substances manufactured into articles which are not used under release promoting condi-  
 239 tions (see ERC 10b/11b), it can be assumed that 100% of M/Is market volume enters into waste  
 240 treatment operations.
- 241 • For substances used in processing aids, the assumption which fraction enters into the waste life  
 242 stage depends on whether the processing aid is disposed of to the sewer (e.g. water based clean-  
 243 ing agents) or released into the air (solvents) from the processing stage. After having assessed  
 244 the earlier life-cycle stages in the CSA, M/I will have sufficient information to make a reason-  
 245 able estimate on the fraction of the substance entering into the waste life stage.
- 246 • For substances in processing aids typically used in closed systems (e.g. motor oils, hydraulic  
 247 fluids), for a Tier 1 exposure estimate it can be assumed that 85% to 95 % enters into the waste  
 248 life stage, taking into account the losses over service life (see nota 5) to ERC 9b in Appendix  
 249 R.16-2)
- 250 • For intermediates and substances reacting on use, only a minor fraction can be expected to enter  
 251 into the waste life stage, since the substance is designed to be consumed in use. It should be as-  
 252 sumed that usually less than 5% of the manufactured volume will enter into emissions including  
 253 waste (see ERC 6 and 8d).

254 Regarding the spatial distribution of emission sources from treatment of the substance amount that  
 255 enters into the waste life stage (fraction of waste life volume), M/I can make the following assump-  
 256 tions:

- 257 • **Treatment of municipal waste and related article waste streams:** Treatment of municipal  
 258 waste (including small industries) can be compared to the discharge of preparation in wide dis-  
 259 perse use to the municipal sewage system. As also suggested in section R16.2.5.1 for releases  
 260 from indoor service life of articles, it can be assumed that the emissions from waste treatment  
 261 operation are released from point sources to local air and water. These point sources are for ex-  
 262 ample municipal waste incinerators, landfills, installations for milling end-of-service-life con-  
 263 sumer equipment (vehicles, electric and electronic articles). The assumption in ERCs on diffu-  
 264 sive emissions at the local scale ('town scenario') is that the local emission is 0.2% of the re-  
 265 gional market volume of articles (fraction of main local source). The number of emission days is  
 266 assumed to be 300 days, like for an industrial installation in continuous operation.
- 267 • **Treatment of hazardous waste and other waste non-municipal waste operations:** To get a  
 268 tier 1 exposure assessment started, the processes can be regarded as industrial point sources  
 269 covered by ERC 1 to 7. This will lead to a very conservative release estimate due to the default  
 270 of 100% regional emission (fraction of main source = 1) and 20 release days. However, wher-  
 271 ever M/I has collected information on the overall number of installations in a typical region, the  
 272 distribution of capacity and the way of operation (continuous or batch), he can overwrite the de-  
 273 fault with more realistic assumptions.
- 274 • **Use of primary or secondary mineral waste in open applications** (e.g. slags from incinera-  
 275 tion, crushed demolition material) as construction material would best be addressed by a re-  
 276 gional scenario based on ERC 10a.

277

**Table R.18-1: Pre-sets for the tier 1 exposure estimate from waste life stage**

	Fraction of substance volume entering into waste life stage (= <i>Fraction of waste life volume</i> )	Fraction of substance in waste treated in one local source (= <i>Fraction of main source from waste life volume</i> )	Emission days
Articles and cured preparations	1	0.002 for municipal treatment + disposal	300 or 365
Processing aids in closed systems	0.85 to 0.95	1	20
Processing aids in open systems	Follows from assessment of previous life cycle stages	1	20
Substances reacted on use	0.05	1	20

278

279

280

281

282

For some waste operations (incineration, solvent recovery), emission calculation modules are being developed by waste industries. M/I is advised to make himself aware on progress made in these developments that could help to replace the conservative release estimations based on ERCs with more realistic emission factors.

283

284

285

286

287

288

289

290

The table in appendix R.18.1 assigns ERCs to a selection of relevant waste treatment operations. In order to carry out an initial tier 1 exposure estimate, the fraction of main source in the selected ERC should be overwritten with the product of *the fraction of waste life volume* multiplied with the *fraction of main source for the treatment operation* (as indicated in Table R.18.1) Also the pre-set emission days can be adjusted accordingly. While at tier 1 assessment, processing of waste can be largely treated like any other industrial or professional processes, there are no specific ERCs yet available for incineration and land-filling. However, the next section also includes advice on a preliminary work-around for this problem.

291

292

293

The subsequent exposure estimation and risk characterization is not different from assessment for other life-cycle stages, and thus does not need particular guidance in the current chapter (see chapter R.16).

294

## **R.18.5.2 Examples for treatment specific pre-sets**

295

### **R.18.5.2.1 Emission from landfills**

296

297

298

299

300

301

302

303

Although various models exist to predict releases from landfills, none of these models is sufficiently checked against reality to suggest substance specific release factors. It is therefore suggested either i) to assume landfills operated under the requirements of the EU landfill directive as safe for any substance properties, volume and waste composition allowed to be land-filled or ii) to treat substances in land-filled article-waste as if this was a prolonged service life (e.g. for construction and demolition waste). Option b) is based on the consideration that landfill of “inert” waste materials will go on in future, and that construction waste landfills are usually operated without top layer sealing. If option b) is to be applied: The release estimation would start from ERC 10a:

304

Fraction of waste life volume: 100%

305

306

307

308

- Fraction of main municipal source: 0.2%
- Release time: 365 days
- Sewage treatment plant: leachate is collected and disposed of in the municipal STP
- Annual release to air: 0.05%

- 309 • Annual release to waste water (before treatment): 3%  
310

311 The releases from landfills and residues from waste incineration residues usually take place over a  
312 long time period, thus the load from the single waste batch is diluted in time. In order however to  
313 take account of the stocking up process of waste in landfills, the emission is projected into 1 year  
314 (accumulated over the waste life stage). The emission factors above assumes a waste life stage un-  
315 der leaching conditions of about 20 years. If available, monitoring data may be a valuable source of  
316 information to refine these assumptions. The need for a long-term release assessment should be de-  
317 cided on a case-by-case basis, in particular for metals or organic substances that are persistent and  
318 toxic.

### 319 **R.18.5.2.2 Emission from incineration and co-incineration**

320 Modern incineration processes can be expected to achieve destruction rates of more than 99.99 %.  
321 For metals emission factors can be calculated from information available in EU Reference Docu-  
322 ment on best Available Techniques for Waste Incineration (August 2006), By comparing average  
323 ranges of metal concentrations in municipal waste with average ranges of metal emission from mu-  
324 nicipal incinerators, the following conservative emission factors to air and water can be derived:

325 **Table R.18-2: Emission factors for metals from municipal waste incinerators<sup>3</sup>**

	To air after abatement (controlled emission)	To water after abatement (controlled emission)
Hg	0.1	0.0002
Cd	0.002	0.0002
As	0.002	0.0002
Pb	0.002	0.0001
Co	0.002	
Ni	0.0003	0.0002
Cr	0.0003	0.0001

326  
327 The emission factors for hazardous waste incineration, municipal waste incineration and co-  
328 incineration in industrial combustion plants do not need to be differentiated at tier 1. For municipal  
329 waste incineration the same pre-set as for land-filling should be applied (except for the emission  
330 factor). For hazardous waste incineration and co-incineration the complete pre-set for a local indus-  
331 trial site should be applied (ERC 1-7). It is assumed that co-incineration takes place in compliance  
332 with the EU Incineration Directive (2000/76/EC)

#### 333 Municipal waste incineration

334 The release estimate should start from ERC<sub>xxx</sub> (to be developed)

- 335 • Fraction of waste life volume: 100%  
336 • Fraction of main source: 0.2%  
337 • Release time: 300 days  
338 • Release to air: 0.01% [organic substance] and 0.2% [metals except mercury]  
339

#### 340 Hazardous Waste incineration and Co-incineration

<sup>3</sup> Documentation see Appendix R.18-4; to be inserted at a later stage.

341

- 342 • Fraction of waste life volume: Depending on technical purpose of the substance; to be deter-
- 343 mined based on the emission during previous life-cycle stages.
- 344 • Fraction of main source: 100%
- 345 • Release time: 20 days
- 346 • Release to air: 0.01% [organic substance] and 0.2% [metals except mercury]

347

#### 348 Recovery of slag from waste incineration

349 Regarding metals, the process aims to include the substance into a matrix (slag) or to filter it out.  
350 Land-filling of secondary waste from waste treatment is not further considered here, but assumed to  
351 be safe by definition. The fraction that leaves the incineration bound into a slag-matrix and which is  
352 likely to be used as construction material needs to be included in release estimates. The most appro-  
353 priate ERC would be again 10a.

### 354 **R.18.5.2.3 Emission from milling vehicles and electric/electronic goods**

355 Dismantling and milling of vehicles, household appliances and electronic goods at the end of there  
356 service life is to be treated as an industrial source. The process aims at homogenization and pelleti-  
357 sation in order to allow for further separation. Dust may be formed and emission on water pathway  
358 could occur if swim-sink operations would be applied. ERC 3 is the most appropriate category  
359 since the substance is included in a matrix and the process aims at homogenization. Significant  
360 emission to air in form of dust can occur:

- 361 • Fraction of waste life volume: 100%
- 362 • Fraction of main municipal source: 0.2%
- 363 • Release time: 300 days
- 364 • Release to air: 0.5%<sup>4</sup>
- 365 • Release to local waste water: 0.2 %

366

#### 367 **Other waste operations**

368 In the same way as here demonstrated for landfill, incineration and dismantling processes, the re-  
369 leases from other waste treatment operations can be estimated. If safe disposal cannot be demon-  
370 strated based on the ERC-pre-sets, further information needs to be collected. This includes OECD  
371 Emission Scenario Documents and the relevant EU BREF Documents (see appendix R.18-1). Also,  
372 some waste industries may prepare emission calculation tools and other information relevant to ex-  
373 posure from waste life stage to support Chemicals Safety Assessment at M/I and the communication  
374 down the chain.

375

---

<sup>4</sup> 30% air emission as in ERC 3 over-conservative for dismantling; to be adjusted to 0.5% based on the EU RAR on DEHP (*Matrix* Report 2006, UBA FKZ 204 67 456/RIVM Report no 60120006, Branch and product related emission estimation tool for manufacturers, importers and downstream users within the REACH system,2006)

388

<sup>10</sup> To be worked out, once the concept is agreed and tested.

389 **APPENDIX R.18-3 – LEGAL REQUIREMENTS**390 Obligations related to substances or preparations recovered from waste

391 Substances recovered from waste and re-introduced into the market (as such, in preparation or arti-  
392 cle) must be registered unless the company can benefit from the exemption of article 2(7) (d). A  
393 registration is not needed under the following conditions:

394 1. The recovered substance has already been registered under REACH. The substance already reg-  
395 istered must be the same, i.e. have the same chemical identity and properties, as the substance  
396 being recovered. For example, if the substance itself was modified in the recovery then the re-  
397 covered substance is not the same and need to be registered: For example, the product from re-  
398 recovery may be

- 399 • a substance as such (e.g. hydrocarbon stream with an EINECS number), which however  
400 contains certain contaminants outside the range of contaminants typical for the registered  
401 substance, or
- 402 • A preparation (including various substances, intentionally combined with each other in the  
403 first life cycle of each of these substances) for which it not possible to relate the major in-  
404 gredients to substances already registered.

406 2. The legal entity that did the recovery must ensure that information on the registered substance is  
407 available to it, and that information must comply with the rules on information provision in the  
408 supply chain. This means that the person who did the recovery must have obtained one of the  
409 following:

- 410 • a safety data sheet, as required by Article 31 (1) or (3), on the registered substance,
- 411 • other information sufficient to enable users to take protection measures, as required by Arti-  
412 cle 31 (4), for the registered substance, or
- 413 • an information package comprising the status of the registered substance under the authori-  
414 sation part of REACH, any applicable restrictions under REACH, other information neces-  
415 sary to allow appropriate risk management measures and the registration number, as re-  
416 quired by Article 32 (1).

418 There are no legal mechanisms foreseen in REACH how to transfer the eSDS or other information  
419 on the registered substance to those companies re-introducing the same substance recovered from  
420 waste onto the market. Manufacturers, downstream users and recycling companies are free to agree  
421 on suitable mechanisms to make such information available to the recycling company.

422 If the material manufactured from waste is re-introduced into the market in form of an article, no  
423 SDS is required, however the REACH requirements according to article 7 may apply: For articles  
424 containing substance of very high concern (identified under article 59) in a concentration > 0.1%  
425 and an amount of > 1t/a per producer, the producer or importer may want to supply instruction to  
426 the recipient of the article on how to handle the article in a way that no exposure will occur during  
427 use, including disposal. Otherwise he would be obliged to notify the article to the Agency and pos-  
428 sibly to register the article on request of the Agency. Under Article 33 the suppliers of articles meet-  
429 ing the above criteria are obliged to sufficiently inform the recipients on safe use, and on the name  
430 of the substance as a minimum.

431 A guidance that particularly addresses the situation of plastic recyclers has been worked out by  
432 EUPC and is contained in an appendix to part G of the cTGD.

## 433 2. Interfaces with other community legislation

434 The assessment of the emission from the waste life stage of a substance under REACH has a par-  
435 ticular interface with community legislation on waste management and integrated pollution preven-  
436 tion and control (IPPC). For example, EU waste legislation and the IPPC Directive set out the re-  
437 quirements for the authorisation of waste treatment operations. Waste treatment operations however  
438 are not covered by REACH, unless the output of that operation is a substance as such, in a prepara-  
439 tion or in an article to be placed on the market (e.g. recycling paper, recovered solvents, recovered  
440 fuels). Companies receiving and treating waste do not have duties to communicate information up  
441 the supply chain under REACH. Thus the access of M/I to information is fundamentally different  
442 compared to the other life cycle stages.

443 The following section provides a brief overview on the relevant community legislation, M/I should  
444 take into account when building the exposure scenario(s) for the waste life stage(s) of his substance:

- 445 • Annex III to Directive 91/689/EEC (Hazardous Waste Directive) sets out a list of criteria and  
446 parameters based on which a waste is to be classified hazardous. Some of these criteria are cop-  
447 ied from the classification rules for preparations (however not as amended by Directive  
448 99/45/EEC). Other criteria are based on waste testing, however harmonised methodology is not  
449 available yet. Under REACH the hazard assessment of the single substance and the assessment  
450 of exposure related to the waste life stage are the basis to characterise the risk, not the classifica-  
451 tion rules for waste under waste legislation.
- 452 • Decision (2000/532/EC) includes a *Harmonised European Waste List*, including classification  
453 of wastes as hazardous or not. The waste classification system is a hybrid of material based  
454 codes and codes indicating the source of waste. Some classes of waste origin are directly com-  
455 patible with the use descriptor system for ES building outlined in section D.3.3 and Appendix  
456 D-1 of the TGD. For example: waste Category 4 (waste from textile, fur and leather process-  
457 ing), waste category (5-7) petroleum and chemical processing, waste category 8 (manufacture,  
458 formulation, supply and use of coatings).
- 459 • The Landfill Directive (1999/31/EC) and the Waste Incineration Directive (2000/76/EC) set out  
460 technical requirements for final disposal of waste, including co-incineration in industrial facili-  
461 ties.
- 462 • Various single Directives set requirements related to the restriction of certain hazardous sub-  
463 stances in certain articles, the separate collection of certain products at end of service life as  
464 well as processing and recycling of certain waste streams, e.g. Waste Electric and Electronic  
465 Equipment (WEEE 2002/96/EC), End-of-Life-Vehicles (2000/53/EC), Batteries and Accumula-  
466 tors (2006/66/EC), Waste Oils (75/439/EEC)
- 467 • Under the IPPC-Directive, information on best available techniques is available for nearly all  
468 common waste treatment techniques in the BREF 08.06 and in BREF 02.03. on *Common Waste*  
469 *Water and Waste Gas Treatment/Management Systems*
  - 470 ○ Handling and treatment of waste resulting from transfer of substances and related  
471 cleaning operations (e.g. floor cleaning from spillage or leakage; cleaning of road  
472 and railway tankers), or cleaning of equipment (e.g. pipe systems, painting equip-  
473 ment, mixing equipment).
  - 474 ○ Biological treatments
  - 475 ○ Chemical-physical treatments
  - 476 ○ Treatments to recover material
  - 477 ○ Treatments to produce fuel material
  - 478 ○ End of pipe waste techniques

- 479           ○ Waste gas treatment techniques, also applicable in waste treatment operations
- 480           ○ Waste water treatment techniques, also applicable in waste treatment operations
- 481

482 The rules and requirements set out in waste legislation and in BREF Documents can be used to  
483 build generic exposure scenarios for waste operations. This regards the applicability of certain tech-  
484 niques to certain waste streams as well as the effectiveness of the measures to destroy, immobilise  
485 or recover the registered substances at the end of their service life.
